Order Fulfillment Process Improvement

Business Analysis Portfolio Project · Process Mapping & Requirements

1. Problem Statement

Customers experience delivery delays without proactive communication, driven by three compounding issues in the current order fulfillment process: payment validation that can take up to an hour, stock levels that are only reconciled on a daily or weekly basis rather than in real time, and a fully manual picking process that adds an average of two days to fulfillment. Related analysis of delivery performance data confirms the business impact of this: orders delivered late score meaningfully lower on customer satisfaction than on-time orders. This document outlines the current process, the specific pain points identified, and the requirements for a future-state process that addresses them.

2. Current State Process

The diagram below shows the process as it exists today, with three pain points identified and marked directly on the flow.

CURRENT STATE: Order Fulfillment Process

Pain Points Identified

1) Payment validation currently takes up to 1 hour before an order proceeds. 2) Stock levels are checked only daily/weekly, not in real time, causing mismatches discovered late. 3) The manual pick process adds an average 2-day delay to fulfillment.

3. Discovery Notes

Simulated stakeholder input, grounded in the pain points identified above:

Finance / Order Processing Lead: "Payment validation can take up to an hour depending on when the order comes in. It's not instant, so there's already a delay before the order even reaches the warehouse."

Warehouse Operations Lead: "We only reconcile stock on a daily or weekly basis, not in real time. So there's a window where the system says an item is available, but it's actually already sold out or misplaced — we don't find out until we try to pick it."

Warehouse Associate: "Picking is still a manual process — we're walking the floor with a paper list. On average that adds about 2 days versus what it could be if picking were more structured or automated."

4. Future State Process

The diagram below shows the proposed process, with the three changed steps highlighted in green.

Future STATE: Order Fulfillment Process

5. Functional Requirements

- FR-1. Payment validation shall complete automatically within 5 minutes of order submission, replacing the current process that can take up to 1 hour.
- FR-2. Inventory levels shall be checked in real time at the moment of order placement, replacing the current daily/weekly stock reconciliation cycle.
- FR-3. Warehouse picking shall be guided by a digital pick-list or barcode-scanning system to reduce the current manual-pick delay, which currently averages 2 days.
- FR-4. The system shall log and report time elapsed at each of the three stages above (payment, stock check, picking) so delays can be monitored on an ongoing basis.

6. Success Metrics

- Reduce payment validation time from up to 60 minutes to under 5 minutes.
- Eliminate stock-mismatch incidents caused by batch inventory checks by moving to real-time sync.
- Reduce average picking time from 2 days to same-day or next-day fulfillment.
- Close the satisfaction gap between on-time and late deliveries by reducing the rate and severity of delays.

7. Out of Scope

- Changes to carrier or shipping partners.
- Warehouse physical layout or facility changes.

8. User Stories

As a customer, I want my payment validated quickly, so that my order starts processing without unnecessary delay.

As a warehouse associate, I want real-time stock visibility instead of daily/weekly checks, so that I never pick an order I can't fulfill.

As a warehouse associate, I want a digital or barcode-guided pick-list, so that I can complete picking faster than the current manual process.

As an operations manager, I want visibility into how much time is spent at each stage (payment, stock check, picking), so that I can identify where future delays are coming from.
